

Intro to Python

Cross-sectional dataset basics

- Data Library
- Import excel file
- Edit data (add column, delete obs, keep variables/observations)
- Summary statistics
- Linear Regression

Example 1: ceosal1

- Read the excel data file (ceosal1.csv) into Python
- Build a local data library to save the Python format data
- Edit data
 - create a new variable: CEO id
 - Create a new dataset that has financial firms only
 - Create a new dataset that removes industrial firm (add column, delete obs, keep variables/observations)
 - Create a new dataset with only salary and another dataset with only firm sales and roe
 - Merge the two datasets
- Summary statistics
 - Sort the observations by salary (low to high vs. high to low)
 - Rank observations into 10 groups by salary
 - Compute the mean, standard deviation, P25, median, P75, Max, Min Salary
- Linear regression
 - Regress salary on ROE
- See S1_Python Intro

HW1 : wage1

- Read the excel data (wage1.csv) file into Python
- Build a local data library to save the Python format data
- Edit data
 - create a new variable: individual id
 - Create a new dataset that has female only
 - Create a new dataset that removes married individuals
 - Create a new dataset with only wage and another dataset with only education and experience
 - Merge the two datasets
- Summary statistics
 - Sort the observations by wage(low to high vs. high to low)
 - Rank observations into 5 groups by wage
 - Compute the mean, standard deviation of salary (for female and male separately)
- Linear Regression
 - Regress wage on education
